16-CHANNEL LED DRIVER

July 2020

GENERAL DESCRIPTION

The IS31FL3726A is an industry standard serial shift-register-plus latch-type LED driver operating from a 3V to 5V supply. It is comprised of 16 constant-current open drain sinks designed for driving common anode LEDs. The output current value can be set from 5mA to 60mA by using an external resistor. As a result, all outputs will have virtually the same current levels. This driver uses a high-speed 4-wire serial interface of up to 30MHz to drive 16 constant current outputs, a 16-bit shift register, a 16-bit latch and a 16-bit AND-gate circuit. Serial input data appears at the output OUTn channels after 16 clock cycles. Driving the Latch pin will load the 16-bit of shift-register data into the 16-bit output latch to drive the LEDs ON or OFF. The Enable pin can be used as a PWM input to adjust the LED brightness. The IS31FL3726A operates from a 3V to 5.5V supply, and is specified over the -40°C to +125°C temperature range.

APPLICATIONS

- Video display panel LED driver
- Point of sale signs
- Variable LED signboards

FEATURES

- Output current capability and number of outputs: 60mA × 16 outputs
- Current set with external resistor
- Constant current range: 5mA to 60mA
 $I_{OUT_MAX} = 45mA @ V_{CC} = 3V$
 $I_{OUT_MAX} = 60mA @ V_{CC} = 5V$
- Current accuracy (All output on, $I_{OUT} = 25.2mA$)
 - Bit to bit: < ±4%.
 - Device to device: < ±2%.
- 200mV LED Dropout at 25mA
- For common-anode LEDs
- Power supply voltage range, $V_{CC} = 3.0V$ to 5.5V
- Serial and parallel data transfer rate: 30MHz (Max. cascade connection)
- Operating temperature range, $T_A = -40^{\circ}C \sim +125^{\circ}C$
- Package: QFN-24 (4mm×4mm), SSOP-24 and eTSSOP-24

PIN DESCRIPTION

No.		Pin	Description
QFN	SSOP/eTSSOP		
1	22	SERIAL-OUT	Output pin for serial data input on SERIAL-IN terminal.
2	23	R-EXT	Input pin connect to an external resistor to regulate the output current.
3	24	VCC	Supply voltage pin.
4	1	GND	GND pin for control logic.
5	2	SERIAL-IN	Input pin for serial data for data shift register.
6	3	CLOCK	Input pin for clock for data shift on rising edge.
7	4	LATCH	Input pin for data strobe when the LATCH input is driven low, data is not latched. When it is pulled high, data is latched.
8 ~ 23	5~20	OUT0~OUT15	Constant-current sinks.
24	21	ENABLE	Input pin for output enable. All current sinks (OUT0 to OUT15) are turned off, when the ENABLE pin is driven High and are turned on, when this pin is driven Low.
		Thermal Pad	Connect to GND.

Conditions: (Refer to test circuit.)

$T_A = 25^\circ\text{C}$, $V_{CC}=V_{IH}=3.3\text{V}$ and 5V , $V_{IL}=0\text{V}$, $R_{EXT}=750\Omega$, $V_L=3.0\text{V}$, $R_L=60\Omega$, $C_L=10.5\text{pF}$

Note 4: Guaranteed by design.

Note 5: I_{OUT} mismatch (bit to bit) ΔI_{MAT} is calculated:

$$\Delta I_{MAT} = \left(\frac{I_{OUTn}(n=0 \sim 15)}{\left(\frac{I_{OUT0} + I_{OUT1} + \dots + I_{OUT15}}{16} \right)} - 1 \right) \times 100\%$$

Note 6: I_{OUT} accuracy (device to device) ΔI_{OUT} is calculated:

$$\Delta I_{OUT} = \left(\frac{\left(\frac{I_{OUT0} + I_{OUT1} + \dots + I_{OUT15}}{16} - I_{OUT(IDEAL)} \right)}{I_{OUT(IDEAL)}} \right) \times 100\%$$

Where $I_{OUT(IDEAL)} = 10.5\text{mA}$ when $R_{EXT} = 1800\Omega$, $I_{OUT(IDEAL)} = 25.2\text{mA}$ when $R_{EXT} = 750\Omega$.

Note 7:

1. If the device is connected in a cascade and t_r/t_f for the waveform is large, it may not be possible to achieve the timing required for data transfer. Please consider the timings carefully.

2. Delay between outputs. The IS31FL3726A has graduated delay circuits between outputs. The fixed delay time is 5ns (typical), $\overline{\text{OUT}}_1$ has 5ns delay, $\overline{\text{OUT}}_2$ has 10ns delay, etc. This delay prevents large inrush currents, which reduce power supply bypass capacitor requirements when the outputs turn on. The delay works during switch on and switch off of each output channel. LEDs that have not turned on before $\overline{\text{ENABLE}}$ is low will still turn on and off at the determined delayed time regardless of the state of $\overline{\text{ENABLE}}$. Therefore, every LED will be illuminated for the amount of time $\overline{\text{ENABLE}}$ is pulled high.

Figure 3 Timing Diagram

Warning: The Latch input is a logic level it is not an edge triggered latch circuit.

Note 8: The serial-in data (SERIAL-IN) will be clocked into a 16 bit shift register synchronized on the rising edge of the clock (CLOCK). The data '1' means the corresponding current output 'ON' for output, the data '0' represents for 'OFF'. The data will be transferred into the 16 bit latch register when the signal (L A T C H) is 'H' (level trigger); otherwise, the data will be latched. The trigger timing of the serial-out data (SERIAL-OUT) will be shifted out on synchronization to the rising edge of the clock. All outputs are turned off while enable terminal (E N A B L E) is kept at high level. And they are active when E N A B L E turns to low.

Truth Table

CLOCK	LATCH	ENABLE	SERIAL-IN	OUT0 ...OUT7 ... OUT15	SERIAL-OUT
	H	L	Dn	Dn ...Dn-7 ...Dn-15	Dn-15
	L	L	Dn+1	No change	Dn-14
	H	L	Dn+2	Dn+2 ...Dn-5 ...Dn-13	Dn-13
	X	L	Dn+3	Dn+2 ...Dn-5 ...Dn-13	Dn-13
	X	H	Dn+3	OFF	Dn-13

Warning: The following conditions, $\overline{\text{ENABLE}}=0$, $\overline{\text{LATCH}}=1$, $\text{SERIAL-IN}=1$, cannot be configured at the same time when power is on, or IS31FL3726A will behave unpredictably.

Note 9: OUT0 to OUT15 =On when Dn = H; OUT0 to OUT15 =Off when Dn = L. In order to ensure that the level of the power supply voltage is correct, an external resistor must be connected between R-EXT and GND.

APPLICATION INFORMATION

ADJUSTING OUTPUT CURRENT

The output current of each channel is set by an external resistor R_{EXT} , the relationship between I_{OUT} and R_{EXT} is:

$$I_{OUT} = k \times \frac{V_{REXT}}{R_{EXT}}$$

Where V_{REXT} is 1.26V, k is 15, so I_{OUT} is calculated by Equation (1):

$$I_{OUT} = 15 \times \frac{1.26V}{R_{EXT}} \quad (1)$$

As show in the figure below:

Figure 5 I_{OUT} vs. R_{EXT}

CONSTANT CURRENT OUTPUT

In order to obtain a good performance of constant-current output, a suitable output voltage is necessary. Users can get related information about the minimum output voltage below.

Figure 6 I_{OUT} vs. V_{OUT}

THERMAL CONSIDERATIONS

The package thermal resistance, θ_{JA} , determines the amount of heat that can pass from the silicon die to the surrounding ambient environment. The θ_{JA} is a measure of the temperature rise created by power dissipation and is usually measured in degree Celsius per watt ($^{\circ}\text{C}/\text{W}$).

When operating the chip at high ambient temperatures, or when driving maximum load current, care must be taken to avoid exceeding the package power dissipation limits. The maximum power dissipation can be calculated using the following Equation (2):

$$P_{D(MAX)} = \frac{T_{J(MAX)} - T_A}{\theta_{JA}} \quad (2)$$

$$\text{So, } P_{D(MAX)} = \frac{125^{\circ}\text{C} - 25^{\circ}\text{C}}{29.1^{\circ}\text{C}/\text{W}} \approx 3.44\text{W (QFN)}$$

$$P_{D(MAX)} = \frac{125^{\circ}\text{C} - 25^{\circ}\text{C}}{70.3^{\circ}\text{C}/\text{W}} \approx 1.42\text{W (SSOP)}$$

$$P_{D(MAX)} = \frac{125^{\circ}\text{C} - 25^{\circ}\text{C}}{28.1^{\circ}\text{C}/\text{W}} \approx 3.56\text{W (eTSSOP)}$$

Figure 7 shows the power derating of the IS31FL3726A on a JEDEC boards (in accordance with JESD 51-5 and JESD 51-7) standing in still air.
